\textbf{Abstract.} In this paper we introduce a paradigm for learning in the limit of potentially infinite languages from all positive data and negative counterexamples provided in response to the conjectures made by the learner. Several variants of this paradigm are considered that reflect different conditions/constraints on the type and size of negative counterexamples and on the time for obtaining them. In particular, we consider the models where 1) a learner gets the least negative counterexample; 2) the size of a negative counterexample must be bounded by the size of the positive data seen so far; 3) a counterexample can be delayed indefinitely. Learning power, limitations of these models, relationships between them, as well as their relationships with classical paradigms for learning languages in the limit (without negative counterexamples) are explored. Several surprising results are obtained. In particular, for Gold’s model of learning requiring a learner to syntactically stabilize on correct conjectures, learners getting negative counterexamples immediately turn out to be as powerful as the ones that do not get them for indefinitely long time (or are only told that their latest conjecture is not a subset, without any specific negative counterexample). Another result shows that for behaviourally correct learning (where semantic convergence is required from a learner) with negative counterexamples, a learner making just one error in almost all its correct conjectures has the “ultimate power”: it can learn the class of all recursively enumerable languages. Yet another result demonstrates that sometimes positive data and negative counterexamples provided by a teacher are not enough to compensate for full positive and negative data.

1 Introduction

Defining a computational model adequately describing learning languages is an important long-standing problem. In his classical paper [Gol67], M. Gold introduced two major computational models for learning languages. One of them, learning from texts, assumes that the learner receives all positive language data, i.e., all correct statements of the language. The other model, learning from informants, assumes that the learner receives all correct statements of the languages,\textsuperscript{* Supported in part by NUS grant number R252-000-127-112.}
as well as all other (incorrect) statements, appropriately labeled as incorrect, that can be potentially formed within the given alphabet. In both cases, a successful learner stabilizes at a correct description of the target language, i.e., a grammar for the target language. J. Barzdin [B74] and J. Case and C. Smith [CS83] introduced a different, more powerful model called behaviorally correct learning. A behaviorally correct learner almost always outputs conjectures (not necessarily the same) correctly describing the target language. An important feature of all these models is that they describe a process of learning in the limit: the learner stabilizes to the correct conjecture (or conjectures), but does not know when it happens. The above seminal models, doubtless, represent certain important aspects of the process of learning potentially infinite targets. On the other hand, when we consider how a child learns a language communicating with a teacher, it becomes clear that these models reflect two extremes of this process: positive data only is certainly less than what a child actually gets in the learning process, while informant (the characteristic function of the language) is much more than what a learner can expect.

D. Angluin, in another seminal paper [Ang88], introduced a different important learning paradigm, i.e., learning from queries to a teacher (oracle). This model, explored in different contexts, including learning languages (see, for example, [LNZ02]), addresses a very important tool available to a child (or any other reasonable learner), i.e., queries to a teacher. However, in the context of learning languages, this model does not adequately reflect the fact that a learner, in the long process of acquisition of a new language, potentially gets access to all correct statements.

In this paper, we combine learning from positive data and learning from queries into a computational model, where a learner gets all positive data and can ask a teacher if a current conjecture (a grammar) does not generate wrong statements (questions of this kind can be formalized as subset queries, cf. [Ang88]). If the conjecture does generate a wrong statement, then the teacher gives an example of such a statement (a negative counterexample) to the learner. In our main model, we assume that the teacher immediately provides a negative counterexample if it exists. However, in practical situations, a teacher may obviously need a lot of time to determine if the current conjecture generates incorrect statements. Therefore, we consider two more variants of our main model that reflect this problem. In the first variant, the teacher is not able to provide a negative counterexample unless there is one whose size does not exceed the size of the longest statement seen so far by the learner. In the second variant, the teacher may delay providing a negative counterexample indefinitely (and, eventually, may even simply answer that the conjecture is wrong, i.e., without providing any negative counterexamples!). Interestingly, while the former model is shown to be weaker than the main model, the latter one turns out to be as powerful as the main model (in terms of capabilities of a learner; we do not discuss complexity issues)!
Our goal in this paper is to explore the new models of learning languages, their relationships, and how they fair in comparison with other popular learning paradigms.

The paper is structured as follows. In Section 2 we introduce necessary notation and basic definitions needed for the rest of the paper. In particular, we define some variants of the classical Gold's model of learning from texts (positive data) and informants (both positive and negative data), \texttt{TxtEx} and \texttt{InfEx}, as well as its behaviorally correct counterpart \texttt{TxtBc} and \texttt{InfBc}.

In Section 3 we define our four models for learning languages from texts and negative counterexamples. In the first, basic, model, a learner is provided a negative counterexample every time when it outputs a hypothesis containing elements not belonging to the target language. The second model is a variant of the basic model when a learner receives the least negative counterexample. The third model takes into account complexity constraints on the teacher. Namely, the learner receives a negative counterexample only if there exists one whose size is bounded by the size of the longest positive example seen in the input so far. The fourth model slightly relaxes the constraint of the model three: the size of the negative counterexample must be bounded by the value of some function applied to the size of the longest positive example in the input. We also introduce non-recursive variants of all four models - when the learner is not necessarily computable.

Section 4 is devoted to \texttt{Ex}-style learning from positive data and negative counterexamples: the learner eventually stabilizes to a correct grammar for the target language. First, in order to demonstrate the power of our basic model, we show that any indexed class of recursively enumerable languages can be learned by a suitable learner in this model. Then we show that the second model is equivalent to the basic model: providing the least negative counterexample does not enhance the power of a learner. Our next major result (Theorem 3) is somewhat surprising: we show that there is a class of languages learnable from informants and not learnable in our basic model. This means that sometimes negative counterexamples are not enough - the learner must have access to all statements not belonging to the language! (This result follows from a more general result for \texttt{Bc}-style learning proved in Section 6). In particular, this result establishes certain constraints on the learning power of our basic model. We also establish a hierarchy of learning capabilities in our basic model based on the number of errors that learner is allowed to have in the final hypothesis. Then we consider the two models with restricted size of negative counterexamples (described above). We show that these models are different and weaker than our basic model. Still we show that these models are quite powerful: firstly, if restricted to the classes of infinite languages, they are equivalent to the basic model, and, secondly there are learnable classes in these models that cannot be learned in classical \texttt{Bc}-model (without negative counterexamples) - even if an arbitrary finite number of errors is allowed in the correct conjectures. In the end of the section we demonstrate that a non-recursive learner in our basic model can learn the class of all recursively enumerable languages. In fact, non-recursive learning with negative
counterexamples turns out to be equivalent to non-recursive learning from informants (in contrast to Theorem 3 for computable learners mentioned above).

In Section 5 we introduce the concept of a locking sequence similar to the one defined in [BB75] for the classical Ex-style learning. As in the case of the classical Ex-model, locking sequences turn out to be useful in characterizing learnability within our model. In particular, locking sequences are employed in our next major surprising result presented in this section. This result (Theorem 16) demonstrates that models of learning from positive data and negative counterexample where the teacher may indefinitely delay providing a negative counterexample (we define four natural versions of them) are still equivalent to the basic model with no delays!

Section 6 is devoted to our Bc-style models. As in the case of Ex-style learning, we show that providing the least negative counterexample does not enhance the power of a learner. We also show that learning with restricted size of negative counterexamples is weaker than the basic model in this setting. In particular, we show that there exists an indexed class of recursively enumerable languages that cannot be learned with negative counterexamples of restricted size (note that all such classes are learnable in our basic Ex-style model as stated in Theorem 1). Then we show that languages learnable in our basic Bc-style model (without errors) are Bc-learnable from informants. In the end we establish one of our most surprising results. First, we demonstrate that the power of our basic Bc-style model is limited: there are classes of recursively enumerable languages not learnable in this model if no errors in almost all (correct) conjectures are allowed. On the other hand, there exists a learner that can learn all recursively enumerable languages in this model with at most one error in almost all correct conjectures! (The learner here needs to find answers to undecidable questions concerning comparison of target and hypothesis languages; the teacher cannot always provide negative counterexamples to the languages different from the target (for example when the conjecture is a subset of the target language), however, by possibly making just one deliberate error, the learner finds a way to encode its questions into conjectures so that the teacher is forced to provide negative counterexamples giving out the necessary information). Based on similar ideas, we obtain some other related results - in particular, that, with one error allowed in almost all correct conjectures, the class of all infinite recursively enumerable languages is learnable in the model with restricted size of negative counterexamples. To prove these results, we developed a new type of learning algorithms, where a learner makes deliberate error in its conjectures to force a teacher to answer questions not directly related to the input language. In contrast to the case with no errors, we also show that when errors are allowed, Bc-learning from informants is a proper subset of our basic model of Bc-learning with errors and negative counterexamples (Corollary 7).
2 Notation and Preliminaries

Any unexplained recursion theoretic notation is from [Rog67]. The symbol $N$ denotes the set of natural numbers, $\{0, 1, 2, 3, \ldots\}$. Symbols $\emptyset$, $\subseteq$, $\subset$, $\supset$, and $\supseteq$ denote empty set, subset, proper subset, superset, and proper superset, respectively. Cardinality of a set $S$ is denoted by $\text{card}(S)$. The maximum and minimum of a set are denoted by $\max(\cdot)$, $\min(\cdot)$, respectively, where $\max(\emptyset) = 0$ and $\min(\emptyset) = \infty$. $L_1 \triangle L_2$ denotes the symmetric difference of $L_1$ and $L_2$, that is $L_1 \triangle L_2 = (L_1 - L_2) \cup (L_2 - L_1)$. For a natural number $a$, we say that $L_1 =^a L_2$, iff $\text{card}(L_1 \triangle L_2) \leq a$. We say that $L_1 =^* L_2$, iff $\text{card}(L_1 \triangle L_2) < \infty$. Thus, we take $n < * < \infty$, for all $n \in N$. If $L_1 =^a L_2$, then we say that $L_1$ is an $a$-variant of $L_2$.

We let $\langle \cdot, \cdot \rangle$ stand for an arbitrary, computable, bijective mapping from $N \times N$ onto $N$ [Rog67]. We assume without loss of generality that $\langle \cdot, \cdot \rangle$ is monotonically increasing in both of its arguments. We define $\pi_1(\langle x, y \rangle) = x$ and $\pi_2(\langle x, y \rangle) = y$.

By $\varphi$ we denote a fixed acceptable programming system for the partial computable functions mapping $N$ to $N$ [Rog67,MY78]. By $\varphi_i$ we denote the partial computable function computed by the program with number $i$ in the $\varphi$-system. Symbol $\mathcal{R}$ denotes the set of all recursive functions, that is total computable functions. By $\Phi$ we denote an arbitrary fixed Blum complexity measure [Blu67,HU79] for the $\varphi$-system. A partial recursive function $\Phi(\cdot, \cdot)$ is said to be a Blum complexity measure for $\varphi$, iff the following two conditions are satisfied:

(a) for all $i$ and $x$, $\Phi(i, x) \downarrow$ iff $\varphi_i(x) \downarrow$.
(b) the predicate: $P(i, x, t) \equiv \Phi(i, x) \leq t$ is decidable.

By convention we use $\Phi_i$ to denote the partial recursive function $\lambda x. \Phi(i, x)$. Intuitively, $\Phi_i(x)$ may be thought as the number of steps it takes to compute $\varphi_i(x)$.

By $W_i$ we denote $\text{domain}(\varphi_i)$. $W_i$, is, then, the recursively enumerable (r.e.) set/language ($\subseteq N$) accepted (or equivalently, generated) by the $\varphi$-program $i$.

We also say that $i$ is a grammar for $W_i$. Symbol $\mathcal{E}$ will denote the set of all r.e. languages. Symbol $L$, with or without decorations, ranges over $\mathcal{E}$. By $\chi_L$ we denote the characteristic function of $L$. By $\overline{L}$, we denote the complement of $L$, that is $\mathcal{N} - L$. Symbol $\mathcal{L}$, with or without decorations, ranges over subsets of $\mathcal{E}$.

By $W_i,s$ we denote the set $\{x < s \mid \Phi_i(x) < s\}$.

We now present concepts from language learning theory. The next definition introduces the concept of a sequence of data.

**Definition 1.** (a) A sequence $\sigma$ is a mapping from an initial segment of $N$ into $(N \cup \{\#\})$. The empty sequence is denoted by $\Lambda$.
(b) The content of a sequence $\sigma$, denoted $\text{content}(\sigma)$, is the set of natural numbers in the range of $\sigma$.
(c) The length of $\sigma$, denoted $|\sigma|$, is the number of elements in $\sigma$. So, $|\Lambda| = 0$.
(d) For $n \leq |\sigma|$, the initial sequence of $\sigma$ of length $n$ is denoted by $\sigma[n]$. So, $\sigma[0]$ is $\Lambda$. 
Intuitively, #’s represent pauses in the presentation of data. We let \( \sigma, \tau, \) and \( \gamma, \) with or without decorations, range over finite sequences. We denote the sequence formed by the concatenation of \( \tau \) at the end of \( \sigma \) by \( \sigma \tau. \) Sometimes we abuse the notation and use \( \sigma x \) to denote the concatenation of sequence \( \sigma \) and the sequence of length 1 which contains the element \( x. \) SEQ denotes the set of all finite sequences.

**Definition 2.** [Gol67] (a) A text \( T \) for a language \( L \) is a mapping from \( N \) into \( (N \cup \{\#\}) \) such that \( L \) is the set of natural numbers in the range of \( T. \) \( T(i) \) represents the \( (i + 1) \)-th element in the text.

(b) The content of a text \( T, \) denoted by \( \text{content}(T), \) is the set of natural numbers in the range of \( T; \) that is, the language which \( T \) is a text for.

(c) \( T[n] \) denotes the finite initial sequence of \( T \) with length \( n. \)

**Definition 3.** A language learning machine from texts [Gol67] is an algorithmic device which computes a mapping from \( \text{SEQ} \) into \( N. \)

**Definition 4.** We say that a recursive function \( I \) is an informant for \( L \) iff for all \( x, \) \( I(x) = \chi_L(x). \)

Intuitively, informants give both all positive and all negative data on the language being learned. \( I[n] \) is the first \( n \) elements of the informant \( I. \) One can similarly define language learning machines from informants.

We let \( M, \) with or without decorations, range over learning machines. \( M(T[n]) \) (or \( M(I[n]) \)) is interpreted as the grammar (index for an accepting program) conjectured by the learning machine \( M \) on the initial sequence \( T[n] \) (or \( I[n] \)). We say that \( M \) converges on \( T \) to \( i, \) (written: \( M(T)_i = i \)) iff \( (\forall n)[M(T[n]) = i]. \) Convergence on informants is similarly defined.

There are several criteria for a learning machine to be successful on a language. Below we define some of them. All of the criteria defined below are variants of the Ex-style and Bc-style learning described in the Introduction; in addition, they allow a finite number of errors in almost all conjectures (uniformly bounded, or arbitrary).

**Definition 5.** [Gol67,CL82] Suppose \( a \in N \cup \{\ast\}. \)

(a) \( M \) \( \text{TEx}^a \)-identifies a text \( T \) just in case \( (\exists i)(W_i =^a \text{content}(T)) \)

(b) \( M \) \( \text{TEx}^a \)-identifies an r.e. language \( L \) (written: \( L \in \text{TEx}^a(M) \)) just in case \( M \) \( \text{TEx}^a \)-identifies each text for \( L. \)

(c) \( M \) \( \text{TEx}^a \)-identifies a class \( \mathcal{L} \) of r.e. languages (written: \( \mathcal{L} \subseteq \text{TEx}^a(M) \)) just in case \( M \) \( \text{TEx}^a \)-identifies each language from \( \mathcal{L}. \)

(d) \( \text{TEx}^a = \{L \subseteq \mathcal{E} | (\exists M)(\mathcal{L} \subseteq \text{TEx}^a(M))\}. \)

**Definition 6.** [CL82] Suppose \( a \in N \cup \{\ast\}. \)

(a) \( M \) \( \text{Bc}^a \)-identifies a text \( T \) just in case \( (\forall n)[W_{M(T[n])} =^a L]. \)

(b) \( M \) \( \text{Bc}^a \)-identifies an r.e. language \( L \) (written: \( L \in \text{Bc}^a(M) \)) just in case \( M \) \( \text{Bc}^a \)-identifies each text for \( L. \)
(c) M \text{TxtBc}^a\text{-identifies a class } \mathcal{L} \text{ of r.e. languages (written: } \mathcal{L} \subseteq \text{TxtBc}^a(\mathcal{M})). \text{ just in case M \text{TxtBc}^a\text{-identifies each language from } \mathcal{L}.

(d) \text{TxtBc}^a = \{L \subseteq \mathcal{E} \mid (\exists M) [L \subseteq \text{TxtBc}^a(\mathcal{M})]\}.

Definition 7. [Gal67,CL82] Suppose \(a \in N \cup \{\ast\}.

(a) M \text{InfEx}^a\text{-identifies } L \text{ (written: } L \in \text{InfEx}^a(L))\text{, just in case for informant } I \text{ for } L, (\exists i) [W_i =^a L \text{ (}\forall \infty n) [M(I[n]) = i].

(b) M \text{InfEx}^a\text{-identifies a class } \mathcal{L} \text{ of r.e. languages (written: } \mathcal{L} \subseteq \text{InfEx}^a(\mathcal{M}))\text{ just in case M \text{InfEx}^a\text{-identifies each language from } \mathcal{L}.

(c) \text{InfEx}^a = \{L \subseteq \mathcal{E} \mid (\exists M) [L \subseteq \text{InfEx}^a(\mathcal{M})]\}.

Definition 8. [CL82] Suppose \(a \in N \cup \{\ast\}.

(a) M \text{InfBc}^a\text{-identifies } L \text{ (written: } L \in \text{InfBc}^a(L))\text{, just in case for informant } I \text{ for } L, (\forall \infty n) [W_M(I[n]) =^a L].

(b) M \text{InfBc}^a\text{-identifies a class } \mathcal{L} \text{ of r.e. languages (written: } \mathcal{L} \subseteq \text{InfBc}^a(\mathcal{M}))\text{ just in case M \text{InfBc}^a\text{-identifies each language from } \mathcal{L}.

(c) \text{InfBc}^a = \{L \subseteq \mathcal{E} \mid (\exists M) [L \subseteq \text{InfBc}^a(\mathcal{M})]\}.

For \(a = 0\), we often write \text{TxtEx, TxtBc, InfEx, InfBc} instead of \text{TxtEx}^0, \text{TxtBc}^0, \text{InfEx}^0, \text{InfBc}^0, \text{respectively}.

\(\mathcal{L}\) \text{ is said to be an } \text{indexed family} \text{ of languages iff there exists an indexing } L_0, L_1, \ldots \text{ of languages in } \mathcal{L} \text{ such that the question } x \in L_i \text{ is uniformly decidable (i.e., there exists a recursive function } f \text{ such that } f(i,x) = \chi_{L_i}(x)).

We let \text{INIT} = \{L \mid (\exists i) [L = \{x \mid x \leq i\}]\}.

3 Learning with Negative Counterexamples

In this section we define four models of learning languages from positive data and negative counterexamples. Intuitively, for learning with negative counterexamples, we may consider the learner being provided a text, one element at a time, along with a negative counterexample to the latest conjecture, if any. One may view this negative counterexample as a response of the teacher to the subset query when it is tested if the language generated by the conjecture is a subset of the target language. One may model the list of negative counterexamples as a second text for negative counterexamples being provided to the learner. Thus the learning machines get as input two texts, one for positive data, and other for negative counterexamples.

We say that \(M(T, T')\) converges to a grammar \(i\), iff for all but finitely many \(n\), \(M(T[n], T'[n]) = i\).

First, we define the basic model of learning from positive data and negative counterexamples. In this model, if a conjecture contains elements not in the target language, then a counterexample is provided to the learner. \text{NC} \text{ in the definition below stands for negative counterexample.}

Definition 9. Suppose \(a \in N \cup \{\ast\}.

(a) M \text{NCEx}^a\text{-identifies a language } L \text{ (written: } L \in \text{NCEx}^a(\mathcal{M}))\text{ iff for all texts } T \text{ for } L, \text{ and for all } T' \text{ satisfying the condition:}
\[ T'(n) \in S_n, \text{ if } S_n \neq \emptyset \text{ and } T'(n) = \#, \text{ if } S_n = \emptyset, \]
where \( S_n = \mathcal{T} \cap W_M(\tau[n], \tau'[n]) \)

\[ M(T, T') \] converges to a grammar \( i \) such that \( W_i =^a L \).

(b) \( M \) \text{NCEx}^a-identifies a class \( \mathcal{L} \) of languages (written: \( \mathcal{L} \subseteq \text{NCEx}^a(M) \)), iff \( M \) \text{NCEx}^a-identifies each language in the class.

(c) \( \text{NCEx}^a = \{ \mathcal{L} \mid (\exists M)[\mathcal{L} \subseteq \text{NCEx}^a(M)] \} \).

We next consider the case when the learner gets the least negative counterexample, rather than any negative counterexample. \text{LNC} in the definition below stands for least negative counterexample.

\textbf{Definition 10.} Suppose \( a \in N \cup \{\ast\} \).

(a) \( M \text{LNCEx}^a \)-identifies a language \( L \) (written: \( L \in \text{LNCEx}^a(M) \)) iff for all texts \( T \) for \( L \), and for all \( T' \) satisfying the condition:

\[ T'(n) = \min(S_n), \text{ if } S_n \neq \emptyset \text{ and } T'(n) = \#, \text{ if } S_n = \emptyset, \]
where \( S_n = \mathcal{T} \cap W_M(\tau[n], \tau'[n]) \)

\[ M(T, T') \] converges to a grammar \( i \) such that \( W_i =^a L \).

(b) \( M \) \text{LNCEx}^a-identifies a class \( \mathcal{L} \) of languages (written: \( \mathcal{L} \subseteq \text{LNCEx}^a(M) \)), iff \( M \) \text{LNCEx}^a-identifies each language in the class.

(c) \( \text{LNCEx}^a = \{ \mathcal{L} \mid (\exists M)[\mathcal{L} \subseteq \text{LNCEx}^a(M)] \} \).

We next consider complexity constraints on the negative counterexample. The negative counterexample is provided only if there exists one such counterexample \( \leq \) the maximum positive element seen in the input so far. This addresses some complexity constraints the teacher may have. \text{BNC} below stands for bounded negative counterexample.

\textbf{Definition 11.} Suppose \( a \in N \cup \{\ast\} \).

(a) \( M \text{BNCEX}^a \)-identifies a language \( L \) (written: \( L \in \text{BNCEX}^a(M) \)) iff for all texts \( T \) for \( L \), and for all \( T' \) satisfying the condition:

\[ T'(n) \in S_n, \text{ if } S_n \neq \emptyset \text{ and } T'(n) = \#, \text{ if } S_n = \emptyset, \]
where \( S_n = \mathcal{T} \cap W_M(\tau[n], \tau'[n]) \cap \{x \mid x \leq \max(\text{content}(T[n])) \} \)

\[ M(T, T') \] converges to a grammar \( i \) such that \( W_i =^a L \).

(b) \( M \) \text{BNCEX}^a-identifies a class \( \mathcal{L} \) of languages (written: \( \mathcal{L} \subseteq \text{BNCEX}^a(M) \)), iff \( M \) \text{BNCEX}^a-identifies each language in the class.

(c) \( \text{BNCEX}^a = \{ \mathcal{L} \mid (\exists M)[\mathcal{L} \subseteq \text{BNCEX}^a(M)] \} \).

The following is a generalization of Definition 11 where the negative counterexample is within some recursive factor of maximum positive element seen so far.

Let \( \text{INCFUNC} = \{ h \in R \mid (\forall x)[h(x) \geq x] \land (\forall x)[h(x) \leq h(x + 1)] \} \). \( \text{INCFUNC} \) is class of non-decreasing functions which are greater than the identity function.

\( \text{BFNC} \) below stands for bounded by a function negative counterexample.
Definition 12. Suppose \( a \in N \cup \{\ast\} \). Suppose \( h \in INCFUNC \).
(a) \( \text{M} \text{BF}^h \text{NCEX}^a \)-identifies a language \( L \) (written: \( L \in \text{BF}^h \text{NCEX}^a(\text{M}) \))
iff for all texts \( T \) for \( L \), and for all \( T' \) satisfying the condition:

\[
T'(n) \in S_n, \text{ if } S_n \neq \emptyset \text{ and } T'(n) = \#; \text{ if } S_n = \emptyset ,
\]

where \( S_n = L \cap W_{M(T[n],T'[n])} \cap \{x \mid x \leq h(\max(\text{content}(T[n])))\} \)

\( \text{M}(T,T') \) converges to a grammar \( i \) such that \( W_i =^a L \).
(b) \( \text{M} \text{BF}^h \text{NCEX}^a \)-identifies a class \( L \) of languages (written: \( L \subseteq \text{BF}^h \text{NCEX}^a(\text{M}) \)), iff \( \text{M} \text{BF}^h \text{NCEX}^a \)-identifies each language in the class.
(c) \( \text{BF}^h \text{NCEX}^a = \{L \mid (\exists M)[L \subseteq \text{BF}^h \text{NCEX}^a(\text{M})]\} \).
(d) \( \text{BFNCEX}^a = \bigcup_{h \in \text{INCFUNC}} \text{BF}^h \text{NCEX}^a \).

Similarly one can define \( \text{NCEx}^a \), \( \text{LNCEx}^a \), \( \text{BNCEx}^a \) and \( \text{BFNCEx}^a \) criteria of inference.

We may also similarly define variants \( \text{NNCEX}^a \), \( \text{NLNCEX}^a \), \( \text{NNBNCEX}^a \), \( \text{NNBFNCEx}^a \) where the learner is allowed to be non-recursive. (Prefix NR to a criteria denotes that learner is allowed to be non-recursive).

Proposition 1. Suppose \( a \in N \cup \{\ast\} \).
(i) \( \text{TtxEx}^a \subseteq \text{BNCEx}^a \subseteq \text{BF}^h \text{NCEX}^a \subseteq \text{NCEx}^a \subseteq \text{LNCEx}^a \).
(ii) \( \text{TtxEx}^a \subseteq \text{BNCEx}^a \subseteq \text{BF}^h \text{NCEx}^a \subseteq \text{NCEx}^a \subseteq \text{LNCEx}^a \).

4 Ex-type Learning With Negative Counterexamples

We first show an example of what can be achieved by using positive data and negative counterexamples in the context of indexed families of languages. Our theorem improves a classical result that every indexed family is learnable from informants. Note that there exist indexed family not in \( \text{TtxEx} \); thus \( \text{Ex} \)-learning without negative counterexample is weaker than \( \text{NCEx} \).

Theorem 1. Suppose \( \mathcal{L} \) is an indexed family. Then \( \mathcal{L} \in \text{NCEx} \).

Proof. Suppose \( L_0, L_1, \ldots \) is an indexed family. On input \((\sigma, \tau)\), \( \text{M} \) outputs a grammar for \( L_i \), for the least \( i \) such that \( \text{content}(\tau) \subseteq L_i \) and \( L_i \cap \text{content}(\tau) = \emptyset \).

Suppose \( T \) is a text for \( L \), and \( j \) is the least number such that \( L_j = L \). Then, for all \( k < j \), either
(i) \( L \not\subseteq L_k \), thus for large enough \( n \), \( \text{content}(T[n]) \not\subseteq L_k \), and thus \( \text{M} \) would not output \( L_k \) as its conjecture, or
(ii) \( L_k - L \neq \emptyset \), thus the first time \( L_k \) is output there will a negative counterexample, and thus \( L_k \) would not be conjectured by \( \text{M} \) thereafter.

Moreover, \( L_j \) always passes both the tests (\( \text{content}(T[n]) \subseteq L_j \) and none of the negative counterexamples are in \( L_j \)). Thus, eventually \( \text{M} \), on text \( T \) and any sequence of valid negative counterexamples, will converge to a grammar for \( L_j \).

We now illustrate another difference between \( \text{NCEx} \) learning and \( \text{TtxEx} \) learning.
Theorem 2. Suppose $\mathcal{L} \in \text{NCEx}$ and $L$ is a recursive language. Then $\mathcal{L} \cup \{L\} \in \text{NCEx}$.

Proof. Suppose $\mathcal{L}$ and $L$ are as in the hypothesis. An \text{NCEx}-learner can learn $\mathcal{L} \cup \{L\}$ as follows. It first outputs a grammar for $L$ and waits until:

(i) it receives a negative counterexample or
(ii) and element in the text not belonging to $L$ (note that this can be recursively checked as $L$ is recursive).

If none of above happens, then clearly input language must be $L$ and the learner identifies it. If one of (i) or (ii) succeeds, then the learner continues with the strategy to \text{NCEx}-identify $\mathcal{L}$. It follows that $\mathcal{L} \cup \{L\} \in \text{NCEx}$. 

Note that above does not hold for \text{TExt}-identification as $\{F \mid F$ is finite$\} \cup \{L\} \not\in \text{TExt}$ for any infinite language $L$ [Gol67].

Also note that Theorem 2 doesn’t generalize to taking r.e. language (instead of recursive language) $L$, as witnessed by $\mathcal{L} = \{\{A \cup \{x\} \mid x \in A\}$, and $L = A$.

Proof. a $\in N \cup \{\ast\}$. Suppose $h \in \text{INCFUNC}$.

(a) $\text{LNECX}^a \subseteq \text{NCEX}^a$.
(b) $\text{NCEX}^a \subseteq \text{InfEX}^a$.
(c) $\text{NCEX}^a \subseteq \text{LANE}^a$.
(d) $\text{BF}^a \text{NCEX}^a \subseteq \text{NCEX}^a$.
(e) $\text{BNCEX}^a \subseteq \text{BF}^a \text{NCEX}^a$.
(f) $\text{TExt}^a \subseteq \text{BNCEX}^a$.

Proof. (a) Note that, for any grammar $i$, one can get the least negative counterexample from arbitrary negative counterexample $y$ by conjecturing grammars for the following languages: $W_g \cap \{x \mid x \leq z\}$, for all different values of $z \leq y$. Note that this search introduces extra mind changes; however this is ok, since for \text{Ex}-type learning, the learner makes only finitely many mind changes.

(b) Note that from an informant one can determine in the limit a negative counterexample, if any, for any grammar $i$. Since for \text{Ex}-type learning the learner only makes finitely many conjectures, part (b) follows.

(c), (d), (e) and (f) easily follow from relevant definitions.

The following corollary shows that using least negative counterexamples, rather than arbitrary negative counterexamples, does not enhance power of a learner - this is applicable also in case when a learner can make a finite bounded number of mistakes in the final conjecture.

Corollary 1. Suppose $a \in N \cup \{\ast\}$. Then, $\text{NCEX}^a = \text{LNECX}^a$.

The next result is somewhat surprising. It shows that sometimes negative counterexamples are not enough: to learn a language, the learner must have access to all negative examples. (In particular, it demonstrates a limitation on the learning power of our basic model).
Theorem 3. \( \text{InfEx} - \text{NCE}^{\ast} \neq \emptyset \).

The above result follows from Theorem 17 and Theorem 18.

We now show the error hierarchy for \( \text{NCE} \)-learning. That is, learning with at most \( n+1 \) errors in almost all conjectures in our basic model is stronger than learning with at most \( n \) errors. The hierarchy easily follows from the following theorem.

Theorem 4. Suppose \( n \in N \).

(a) \( \text{TtxEx}^{n+1} - \text{NCE}^{n} \neq \emptyset \).

(b) \( \text{TtxEx}^{\ast} - \bigcup_{n \in N} \text{NCE}^{n} \neq \emptyset \).

Proof. (a) Follows from \( \text{TtxEx}^{n+1} - \text{InfEx}^{n} \neq \emptyset \) [CL82] and Proposition 2(b).

(b) Follows from \( \text{TtxEx}^{\ast} - \bigcup_{n \in N} \text{InfEx}^{n} \neq \emptyset \) [CL82] and Proposition 2(b).

As, by Proposition 2, \( \text{TtxEx}^{n+1} \subseteq \text{BNCEx}^{n+1} \subseteq \text{BFBNCE}^{n+1} \subseteq \text{NCE}^{n+1} \subseteq \text{LNCE}^{n+1} \), the following corollary follows from Theorem 4.

Corollary 2. Suppose \( n \in N \) and \( h \in \text{INCFUNC} \).

(a) \( \text{NCE}^{n} \subseteq \text{NCE}^{n+1} \).

(b) \( \text{LNCE}^{n} \subseteq \text{LNCE}^{n+1} \).

(c) \( \text{BF}^{h}\text{NCE}^{n} \subseteq \text{BF}^{h}\text{NCE}^{n+1} \).

Now we demonstrate yet another limitation on the learning power of our basic model when an arbitrary finite number of errors is allowed in the final conjecture; there are languages learnable within the classical \( \text{Bc} \)-style model (without negative counterexamples) and not learnable in the above variant of our basic model.

Theorem 5. \( \text{TtxBc} - \text{NCE}^{\ast} \neq \emptyset \)

Proof. Follows from \( \text{TtxBc} - \text{InfEx}^{\ast} \neq \emptyset \) [CL82] and Proposition 2(b).

We will use the following proposition in some of our theorems.

Proposition 3. [Go67] Suppose \( L_{0}, L_{1}, \ldots \) and \( L \) are such that (i) for all \( i \), \( L_{i} \subseteq L_{i+1} \), and (ii) \( \bigcup_{i \in N} L_{i} = L \). Then, \( \mathcal{L} = \{ L \} \cup \{ L_{i} | i \in N \} \notin TtxBc^{\ast} \) (even if one allows non-recursive learners).

Now we turn to models where size of negative counterexamples is restricted: \( \text{BNCEx} \) and \( \text{BF}^{h}\text{NCE} \).

We first show that there are classes of languages learnable in our basic model that cannot be learned in any of the models that use negative counterexamples of limited size - even if the learners in the latter models are non-computable.

Theorem 6. \( \text{NCE} - \bigcup_{h \in \text{INCFUNC}} \text{NRBF}^{h}\text{NCE}^{\ast} \neq \emptyset \).
Proof. We assume without loss of generality that pairing function is increasing in both its arguments. For \( \varphi_i \in INCFUNC \), let \( x_i^0 = \langle i, \emptyset \rangle \). Let \( x_i^{j+1} = \langle i, \varphi_i(x_i^j) + 1 \rangle \). Now let \( L_i^k = \{ \langle i, x_i^j \rangle \mid j \leq k \} \), and \( L_i^N = \{ \langle i, x_i^j \rangle \mid j \in N \} \). For \( \varphi_i \in INCFUNC \), let \( \mathcal{L}_i = \{ L_i^k \mid k \in N \} \cup \{ L_i^N \} \). Let \( \mathcal{L} = \bigcup_{i \in \varphi_i \in INCFUNC} \mathcal{L}_i \).

Now we show that \( \mathcal{L} \in NCEx \). A learner can first determine \( i \) such that input is a language from class \( \mathcal{L}_i \). Then the learner can output a grammar for \( L_i^N \). If there is no negative counterexample to this conjecture, then we are done; otherwise the learner can follow the strategy of learning finite languages from text to learn the input language.

We now claim that \( \mathcal{L}_i \not\in NRBF^{\varphi_i}NCEx^* \), for any \( \varphi_i \in INCFUNC \). To see this, note that for learning languages in \( \mathcal{L}_i \), according to criterion \( NRBF^{\varphi_i}NCEx^* \), the negative information is not useful as every \( L_i^k \subseteq L_i^N \) and \( \min(L_i^N - L_i^k) > \varphi_i(\max(L_i^k)) \). Thus, \( \mathcal{L}_i \not\in NRBF^{\varphi_i}NCEx^* \), follows from \( \mathcal{L}_i \not\in \text{TxtEx}^* \), even for non-recursive learner (this follows by Proposition 3, as for all \( k \), \( L_i^k \subseteq L_i^{k+1} \) and \( \bigcup_{k \in N} L_i^k = L_i^N \).)

However, the following theorem shows that if attention is restricted to only infinite languages, then \( NCEx \) and \( BNCEX \) behave similarly.

**Theorem 7.** Suppose \( \mathcal{L} \) consists of only infinite languages. Then \( \mathcal{L} \in NCEx^a \) if \( \mathcal{L} \in BNCEX^a \).

**Proof.** As \( BNCEX^a \subseteq NCEx^a \), it suffices to show that if \( \mathcal{L} \in NCEx^a \) then \( \mathcal{L} \in BNCEX^a \). Suppose \( M \) \( NCEx^a \)-identifies \( \mathcal{L} \). Define \( M' \) as follows. \( M' \) on the input text \( T \) of positive data for an infinite language \( L \) behaves as follows. Initially let \( \text{Cntrexmlps} = \emptyset \). Intuitively, \( \text{Cntrexmlps} \) denotes the set of negative counterexamples received so far. Initially let \( \text{NegSet} = \emptyset \). Intuitively, \( \text{NegSet} \) denotes the set of grammars for which we know a negative counterexample. For \( j \in \text{NegSet} \), \( nceX(j) \) would denote a negative counterexample for \( j \). For ease of presentation, we will let \( M' \) output more than one conjecture (one after another) at some input point and get negative counterexamples for each of them. This is for ease of presentation and one can always spread out the conjectures.

**Stage s (on input \( T[s] \))**
1. Simulate \( M \) on \( T[s] \), by giving negative counterexamples to any conjectures \( j \in \text{NegSet} \), \( nceX(j) \). Other grammars get \( \# \) as counterexample.
2. Let \( S \) be the set of conjectures output by \( M \), in the above simulation, on initial segments of \( T[s] \), and let \( k \) be the final conjecture.
3. If \( k \not\in \text{NegSet} \), output a grammar for \( \bigcup_{i \in S - \text{NegSet}} W_i \),
   Otherwise (i.e., if \( k \in \text{NegSet} \)), output a grammar for \( [(W_k - \text{Cntrexmlps}) \cup \bigcup_{i \in S - \text{NegSet}} W_i] \).
4. If there is no negative counterexample, then go to stage \( s + 1 \).
5. Else (i.e., there is a negative counterexample) output one by one, for each \( i \in S - \text{NegSet} \), grammar \( i \). If a negative counterexample is obtained, then place \( i \) in \( \text{NegSet} \) and define \( nceX(i) \) to be this negative counterexample.
   (Note that since \( M' \) is for \( BNCEX \)-type learning, negative examples received would be \( \leq \max(\text{content}(T[s])) \), if any).
Update Cntreexamples based on new negative counterexamples obtained.
6. Go to stage $s + 1$.
End Stage $s$.

Now let $T$ be a text for infinite language $L \in \mathcal{L}$. Let $\text{NegSet}^f$ denote the set of all elements which are ever placed in $\text{NegSet}$ in the above construction. For the text $T$, let $\text{Neg}_T$ denote the text for negative counterexamples generated as follows:

$$\text{Neg}_T(i) = \begin{cases} \text{nceax}(\mathcal{M}(T[i], \text{Neg}_T[i])), & \text{if } \mathcal{M}(T[i], \text{Neg}_T[i]) \in \text{NegSet}^f; \\
\#, & \text{otherwise.} \end{cases}$$

We claim that $\text{Neg}_T$ denotes a correct text for negative counterexamples (for NCEx-a-model of learning) when $\mathcal{M}$ is fed $T$ as the positive data text. Clearly, if a negative counterexample is provided above then it is correct. So we only need to consider if there exists an $i$ such that $\mathcal{M}(T[i], \text{Neg}_T[i]) \notin \text{NegSet}^f$, but $W_{\mathcal{M}(T[i], \text{Neg}_T[i])} \notin L$. We claim that this is not possible. To see this suppose, by way of contradiction, that $i$ is the least number for which this happens. Then, beyond some stage (by which stage all $\mathcal{M}(T[j], \text{Neg}_T[j])$ $j < i$, such that $W_{\mathcal{M}(T[j], \text{Neg}_T[j])} \notin L$, have been placed in $\text{NegSet}$), we have that the above construction will output a grammar which enumerates at least $W_{\mathcal{M}(T[i], \text{Neg}_T[i])}$ (see step 3). Thus, eventually a negative counterexample to $W_{\mathcal{M}(T[i], \text{Neg}_T[i])}$ would appear due to steps 3 and 5 (as the data in the input text is unbounded, due to $L$ being infinite set). A contradiction. Thus, $\text{Neg}_T$ denotes a correct sequence of negative counterexamples to $\mathcal{M}$ on text $T$.

Thus, since $\mathcal{M}$ converges on $(T, \text{Neg}_T)$, we have that for all but finitely many stages, the simulation of $\mathcal{M}$ in step 1 is correct (i.e., $\mathcal{M}'$ provides the correct negative counterexamples, if any, in the simulation). Thus, for all but finitely many stages, as $\mathcal{M}$ NCEx-a-identifies $L$, the grammar output in step 3 by $\mathcal{M}'$ would be correct (except for possibly $a$ errors of omission, as done by the final grammar of $\mathcal{M}$) and $\mathcal{M}'$ BNCEEx-a-identifies $L$.

Our next result shows that the model BNCEx, while being weaker than our basic model, is still quite powerful: there are classes of languages learnable in this model that cannot be learned in the classical Bc-style model even when an arbitrary finite number of errors is allowed in almost all conjectures.

**Theorem 8.** \(\text{BNCEx} - \text{TxtBc}^* \neq \emptyset\).

*Proof.* Let $E = \{2x \mid x \in N\}$, the set of even numbers. Let $L_n = E \cup \{x \mid x \leq n\}$. Consider the class $\mathcal{L} = \{N\} \cup \{L_n \mid n \in N\}$. Clearly, $\mathcal{L} \in \text{BNCEx}$ as one can output a grammar for $N$ until, if ever, there is a negative counterexample. If and when a negative counterexample is received for $N$, one can then follow the strategy to learn $\{L_n \mid n \in N\}$ (which is learnable from text alone). However, as $L_1 \subset L_3 \subset L_5 \ldots$ and $\bigcup_{i \in N} L_{2i+1} = N$, we have from Proposition 3 that $\mathcal{L} \notin \text{TxtBc}^*$ (even by non-computable learners).

The next result shows that BF\textsuperscript{h}NCEx allows one to learn a class which is not learnable in BNCEx model, even if a BNCEx-learner is not computable.
Theorem 9. Suppose \( h \) is such that for all \( x \), \( h(x) > x \). Then \( \text{BF}^{h} \text{NCEX} - \text{NRBNCEX}^{*} \neq \emptyset \).

Proof. Consider \( \mathcal{L} = \text{INIT} \cup \{N\} \). We first show that \( \mathcal{L} \in \text{BF}^{h} \text{NCEX} \). A learner can output a grammar for \( N \) until, if ever, there is a negative counterexample. (Note that if the input language is \( \{x \mid x \leq n\} \), for some \( n \), then elements in \( \{x \mid n < x \leq h(n)\} \neq \emptyset \), are valid negative counterexamples for the language \( N \), once element \( n \) appears in the input). If and when a negative counterexample is received for \( N \), one can then follow the strategy to learn \( \text{INIT} \), which is learnable from text alone.

On the other hand, for \( \text{NRBNCEX}^{*} \) learnability, there is never a negative counterexample, as none of the languages in the class have a negative counterexample \( \leq \) maximum element present in the input. Thus, using Proposition 3, we have that \( \mathcal{L} \notin \text{NRBNCEX}^{*} \).

Now we show a hierarchy for \( \text{BF}^{h} \text{NCEX} \)-style learning. If \( h' \) is greater than \( h \) in just infinitely many points, then \( \text{BF}^{h'} \text{NCEX} \) contains languages not learnable in \( \text{BF}^{h} \text{NCEX} \), even if a \( \text{BF}^{h} \text{NCEX} \)-learner is non-computable.

Theorem 10. Suppose \( h, h' \in \text{INCFUNC} \). Suppose further that \( x_{0}, x_{1}, \ldots \) is a recursive sequence of increasing numbers such that

(i) \( x_{0} = 0 \)

(ii) for all \( i \), \( h(x_{2i+1}) < x_{2i+2} \leq h'(x_{2i+1}) \).

Let \( L_{N} = \{x \mid (\exists i)(x_{2i} \leq x \leq x_{2i+1})\} \).

Let \( L_{j} = \{x \mid (\exists j)(x_{2j} \leq x \leq x_{2j+1})\} \).

Then, \( \mathcal{L} = \{L_{j} \mid j \in N\} \cup \{L_{N}\} \in \text{BF}^{h'} \text{NCEX} - \text{NRBF}^{h} \text{NCEX}^{*} \).

Proof. Clearly \( \mathcal{L} \in \text{BF}^{h} \text{NCEX} \), as one can output a grammar for \( L_{N} \) until, if ever, a negative counterexample is received. (Note that if input language is \( L_{j} \), then eventually there exists such a negative counterexample as \( x_{2j+2} \in L_{N} - L_{j} \) and \( x_{2j+2} \leq h'(x_{2j+1}) \).) If and when a negative counterexample is received, the learner can then follow the learning strategy (similar to that for \( \text{INIT} \)) for \( \{L_{j} \mid j \in N\} \) (which can be learned from text alone).

On the other hand, for \( \text{NRBF}^{h} \text{NCEX}^{*} \) learnability there is never a negative counterexample from the set \( L_{N} \) due to the fact that \( \min(L_{N} - L_{j}) > h(\max(L_{j})) \) for any \( j \in N \). This essentially renders the negative information useless. Thus \( \mathcal{L} \notin \text{NRBF}^{h} \text{NCEX}^{*} \) would mean \( \mathcal{L} \notin \text{TXT}^{*} \) (by non-computable learner), which is not true by Proposition 3 (as \( L_{j} \subseteq L_{j+1} \) and \( \bigcup_{j \in N} L_{j} = L_{N} \)).

Corollary 3. Suppose \( h, h' \in \text{INCFUNC} \) such that \( h'(x) > h(x) \) for infinitely many \( x \). Then \( \text{BF}^{h'} \text{NCEX} - \text{NRBF}^{h} \text{NCEX}^{*} \neq \emptyset \).

Proof. Note that, for any pair of recursive functions \( h \) and \( h' \) such that \( h'(x) > h(x) \) for infinitely many \( x \), one can define a recursive sequence of \( x_{i} \) such that hypotheses (i) and (ii) in Theorem 10 hold. This can be done by taking \( x_{0} = 0 \) and inductively defining \( x_{2i+1}, x_{2i+2} \) such that \( x_{2i+1} > x_{2i} \) and \( h(x_{2i+1}) < h'(x_{2i+1}) = x_{2i+2} \). Now corollary follows from Theorem 10.
On the other hand, if \( h'(x) \leq h(x) \) for all but finitely many \( x \), then clearly \( \text{BF}^\text{NCEx}^a \subseteq \text{BF}^\text{hNCEx}^a \).

We now turn our attention to the power of non-computable learners. The following proposition follows from definitions.

**Proposition 4.** Suppose \( a \in N \).

(a) \( \text{NRNCEx}^a \subseteq \text{NRLNCEx}^a \).

(b) \( \text{NRBFNCE}^a \subseteq \text{NRNCEx}^a \).

(c) \( \text{NRBNCE}^a \subseteq \text{NRFBNCE}^a \).

As the next result shows, a non-computable learner in our basic model has the "ultimate power": it can learn all recursively enumerable languages.

**Theorem 11.** \( \mathcal{E} \in \text{NRNCEx} \).

**Proof.** A non-effective learner can search for the least grammar \( i \) such that \( \text{content}(T) \subseteq W_i \) and \( i \) does not generate a negative counterexample. Thus, \( \mathcal{E} \in \text{NRNCEx} \). \[ \square \]

As \( \mathcal{E} \in \text{NRInfEx} \), we have

**Corollary 4.** \( \text{NRNCEx} = \text{NRInfEx} \).

**Theorem 12.** Suppose \( \mathcal{L} \) is such that:

for any infinite \( L \in \mathcal{L} \), there exist only finitely many \( n \) such that \( L \cap \{ x \mid x < n \} \in \mathcal{L} \).

Then, \( \mathcal{L} \in \text{NRBNCE} \).

**Proof.** Define (possibly nonrecursive) \( M \) as follows. On input \( (T[n], T'[n]) \), output the least \( i \) such that

(i) \( \text{content}(T[n]) \subseteq W_i \),

(ii) \( \text{content}(T'[n]) \cap W_i = \emptyset \),

(iii) \( W_i = \text{content}(T[n]) \) or for some \( t \), \( \text{content}(T[n]) = W_i \cap \{ x \mid x < t \} \) and \( \text{content}(T[n]) \notin \mathcal{L} \).

We claim that above \( M \) would \( \text{NRBNCE} \)-identify \( \mathcal{L} \). To see this suppose \( T \) is a text for \( L \in \mathcal{L} \). Let \( i \) be the least grammar for \( L \). If \( L \) is finite, then let \( n \) be such that \( \text{content}(T[n]) = L \). If \( L \) is infinite, then let \( t \) be such that for all \( t' \geq t \), \( W_i \cap \{ x \mid x < t' \} \notin \mathcal{L} \); then let \( n \) be such that \( W_i \cap \{ x \mid x < t \} \subseteq \text{content}(T[n]) \).

Now, for \( n' \geq n \), \( i \) satisfies conditions (i)---(iii) above. Thus, \( M(T[n']) \leq i \).

Now, for any \( j < i \), let \( n' > n \) be so large that:

(iv) if \( L \notin W_j \), then \( T[n'] \notin W_j \),

and

(v) if \( \min(W_j - L) \leq \max(L) \), then \( \min(W_j - L) \leq \max(T[n']) \).

Note that there exists such an \( n' \).

We claim that, any \( j < i \) appears at most once as a conjecture beyond \( T[n'] \). Clearly, if \( L \notin W_j \), then \( j \) cannot appear as \( M \)'s conjecture beyond \( T[n'] \) due to (i) and (iv) above. Furthermore, if \( \min(W_j - L) \leq \max(L) \), then \( j \) appears at most once beyond \( T[n'] \) (as then we will get a negative counterexample for
conjecture \( j \). Thus, for \( j \) to appear more than once beyond \( T[n'] \), we must have \( L \subseteq W_j \) and \( \min(W_j - L) > \max(L) \). But then \( L \) is finite, and \( W_j \cap \{ x \mid x < \max(L) \} = L \). Thus, (iii) above implies that \( j \) would not be output by \( M \) beyond \( T[n'] \).

Also, since \( i \) satisfies (i)—(iii) above, for \( n'' \geq n' \), we would have that \( M \) outputs \( i \).

**Theorem 13.** Suppose \( \mathcal{L} \) is such that:

there exists an infinite \( L \in \mathcal{L} \), there exist infinitely many \( n \) such that \( L \cap \{ x \mid x < n \} \in \mathcal{L} \).

Then, \( \mathcal{L} \notin \text{NRBNCBc}^* \).

**Proof.** Suppose \( \sigma \) is a \( \text{NRBNCBc}^* \)-locking sequence for (possibly non-recursive) \( M \) on \( L \). Let \( t \) be such that \( \text{content}(\sigma) \subseteq L \cap \{ x \mid x < t \} \) and \( L \cap \{ x \mid x < t \} \in \mathcal{L} \). Now, \( M \) cannot \( \text{NRBNCBc}^* \)-identify \( L \cap \{ x \mid x < t \} \), on a text \( T, \sigma \subseteq T \), for \( L \cap \{ x \mid x < t \} \).

Note that Theorems 12 and 13 give a characterization for \( \text{NRNCEX} \)-identification and also show that \( \text{NRBNCEX} = \text{NRBNCBc}^* \).

One can similarly show:

**Theorem 14.** Fix \( h \in \text{INCFUNC} \). Suppose \( \mathcal{L} \) is such that:

for any infinite \( L \in \mathcal{L} \), there exist only finitely many \( n \in L \) such that \( L \cap \{ x \mid x \leq n \} \in \mathcal{L} \), but \( \min(L - \{ x \mid x \leq n \}) > h(n) \).

Then, \( \mathcal{L} \notin \text{NRBF}_{h}^* \text{NCEX} \).

**Theorem 15.** Fix \( h \in \text{INCFUNC} \). Suppose \( \mathcal{L} \) is such that:

there exists an infinite \( L \in \mathcal{L} \), for infinitely many \( n \in L \), \( L \cap \{ x \mid x \leq n \} \in \mathcal{L} \), and \( \min(L - \{ x \mid x \leq n \}) > h(n) \).

Then, \( \mathcal{L} \notin \text{NRBF}_{h}^* \text{NCEX} \).

### 5 Locking Sequence and Delayed Counterexamples

In this section we introduce the concept of a locking sequence for our \( \text{Ex} \)-style learning model. Locking sequence (see [BB75]) is an important tool in understanding and characterizing learning languages in the limit. Informally, a locking sequence is an initial fragment of the input text that is sufficient for a learner to identify the target language. Once the locking sequence has been inputted, the learner never changes its mind. Using the concept of locking sequence, we obtain a characterization of \( \text{NCEX} \)-type learning. Our concept of locking sequence turns out to be very useful in our following discussion of learning from positive data and negative counterexamples when counterexamples can be indefinitely delayed.
For the following, we will often consider giving machine $M$ least valid negative information, if any. To this end, we will define a sequence $\text{neginput}_{M,L,\sigma}$ as follows:

$$
\text{neginput}_{M,L,\sigma}(n) = \begin{cases} 
\#, & \text{if } W_M(\sigma[n], \text{neginput}_{M,L,\sigma}[n]) \subseteq L; \\
x, & \text{otherwise,}
\end{cases}
$$

where $x = \min(W_M(\sigma[n], \text{neginput}_{M,L,\sigma}[n]) - L)$.

(for $\text{BNCEx}$, $\text{BF}^4\text{NCEx}$ identification the first clause above is appropriately modified to check containment only for elements $\leq \max(\text{content}(\sigma))$ or $h(\max(\text{content}(\sigma)))$ respectively).

When the input language $L$ is implicit, we also define $\text{LN}_M(\sigma) = M(\sigma, \text{neginput}_{M,L,\sigma}[\sigma])$.

Intuitively, $\text{LN}$ above stands for least negative relevant counterexample given.

**Definition 13.** $(\sigma, j)$-is said to be a $\text{NCEx}$-stabilizing sequence for $M$ on $L$ iff

(i) $\text{content}(\sigma) \subseteq L$,

(ii) $W_{\text{LN}_M(\sigma)} \subseteq L$,

(iii) For all $\tau$ such that $\text{content}(\tau) \subseteq L$, $\text{LN}_M(\sigma) = \text{LN}_M(\sigma \tau)$.

(iv) For all $n \leq |\sigma|$, $\min(W_{\text{LN}_M(\sigma[n])} \cap L) = \min(W_{\text{LN}_M(\sigma[n]), j} \cap L)$.

(For $\text{BNCEx}$-stabilizing sequence above definition is appropriately modified by changing (ii) and (iv) to)

(ii') $W_{\text{LN}_M(\sigma)} \cap \{x \mid x \leq \max(L)\} \subseteq L$,

(iv') For all $n \leq |\sigma|$, $\min(W_{\text{LN}_M(\sigma[n])} \cap L \cap \{x \mid x \leq \max(\text{content}(\sigma[n]))\}) = \min(W_{\text{LN}_M(\sigma[n]), j} \cap L \cap \{x \mid x \leq \max(\text{content}(\sigma[n]))\})$.

**Remark:** Recall that $W_{i,j} = \{x \mid x < j \land \Phi_i(x) < j\}$. Thus $W_{i,j} \subseteq \{x \mid x < j\}$.

Note that if $(\sigma, j)$ is a stabilizing sequence for $M$ on $L$, then so is $(\sigma', j')$, for any $j' \geq j$, and $\tau' \supseteq \tau$ with $\text{content}(\tau') \subseteq L$.

**Definition 14.** $(\sigma, j)$-is said to be a $\text{NCEx}$-locking sequence for $M$ on $L$ iff

(i) $(\sigma, j)$ is a stabilizing sequence for $M$ on $L$, and

(ii) $\text{LN}_M(\sigma)$ is a grammar for $L$.

**Proposition 5.** Suppose $M$ $\text{NCEx}$-identifies $L$. Then

(a) there exists a $\text{NCEx}$-stabilizing sequence for $M$ on $L$, and

(b) every $\text{NCEx}$-stabilizing sequence for $M$ on $L$ is also a $\text{NCEx}$-locking sequence for $M$ on $L$.

**Proof.** (a) Consider the process in which $M$ is always given the least negative counterexample, if any. We first claim that there exists a $\tau$ such that

(i) $\text{content}(\tau) \subseteq L$, (ii) $W_{\text{LN}_M(\tau)} \subseteq L$, and (iii) for any $\tau' \supseteq \tau$ such that $\text{content}(\tau') \subseteq L$, $\text{LN}_M(\tau) = \text{LN}_M(\tau')$. This follows immediately from the fact that $M$ $\text{NCEx}$-identifies $L$. (Otherwise, one can construct a text $T$ such that (I) $M$ does not converge on $T$ or (II) $M$ makes infinitely many wrong conjectures on $T$. To see this, let $T'$ be a text for $L$. Define $\tau_0$ as follows. $\tau_0$ is a sequence consisting of just $T'(0)$. Inductively define $\tau_{i+1}$ as follows. If $\tau_i$ does not satisfy the requirements (i)-(iii), then either (I') for some $\sigma$ extending $\tau_i$ with
content(σ) ⊆ L, LN_M(τ_i) ≠ LN_M(σ), or (ii') W_{LN_M(τ_i)} contains an element outside L — in this case let σ = τ_i. Now let τ_{i+1} = σT(i + 1). It immediately follows that ∪_{i∈N} τ_i is a text for L, and LN_M(T) makes infinitely many mind changes on T or makes infinitely many wrong conjectures on T.)

Now define j to be the least value such that, for all n ≤ |τ|, \(\min(W_{LN_M(τ[n])} \cap L) = \min(W_{LN_M(τ[n])}, j \cap L)\).

Now, (τ, j) satisfies the definition of being NCEx-stabilizing sequence for M on L.

(b) Follows from definition of NCEx-identification.

The following proposition demonstrates how learning in our basic model can be characterized using locking sequences.

**Proposition 6.** \(L ∈ \text{NCEx}\) iff there exists an M such that for each \(L ∈ L\),

(a) there exists a NCEx-stabilizing sequence for M on L, and

(b) every stabilizing sequence for M on L is a NCEx-locking sequence for M on L.

**Proof.** Left to Right direction follows from Proposition 5.

For right to left part note that a NCEx-learner M' can search for a (σ, j) such that the following properties are satisfied:

(i) content(σ) ⊆ L,

(ii) W_{LN_M(σ)} ⊆ L,

(iii) For all τ such that content(τ) ⊆ L, LN_M(σ) = LN_M(στ).

(iv) For all n ≤ |σ|, \(\min(W_{LN_M(σ[n])} \cap L) = \min(W_{LN_M(σ[n])}, j \cap L)\).

Note that a NCEx learner can determine \(χ_L[\bar{j}]\) (by conjecturing grammars for \(\{i\}, i ≤ j\)). Thus, second part of the equality in (iv) above can be effectively determined, and thus any violation of (iv) can be determined in r.e. sense (by outputing LN_M(σ[n]) and, if there is a negative counterexample, enumerating W_{LN_M(σ[n])} and checking the elements in L \(\cap \{x \mid x < j\}\)). Assuming (iv) holds, negative information needed for calculating W_{LN_M(τ)}, for τ ⊆ σ, can also be effectively found using \(χ_L[\bar{j}]\). Violation of (ii) can be determined by checking if conjecturing LN_M(σ) leads to a negative example. Violation of (iii) is easy to check. Thus, in the limit, we can find a stabilizing sequence for M on L, if any. Hence, a learner can output LN_M(σ), in the limit, for one such stabilizing sequence (which gives a grammar for L by clause (b)).

For BNCEX-identification we have the following characterization. The proof is similar to the above proposition, except that we need a slight modification as one may not be able to determine \(χ_L[\bar{j}]\) from the input (due to extra constraints on negative examples). Similar characterization results can be proved for BF^hNCEx-identification also.

**Proposition 7.** \(L ∈ BNCEX\) iff there exists an M such that for each \(L ∈ L\),

(a) there exists a BNCEX-stabilizing sequence for M on L, and

(b) every stabilizing sequence for M on L is a BNCEX-locking sequence for M on L.
Proof. Left to Right direction follows by using an analogue of Proposition 5.

For Right to Left direction we proceed similar to Proposition 6, except that
we need to be careful in the sense that one may not be able to obtain $\chi_L[j]$ 
from the input, if the input language is finite (due to constraints on the negative
information provided).

Thus, on input $T$, a $\text{BNCEx}$ learner $M'$ searches for a $(\sigma, j)$ such that:
(I) $\text{content}(T) \subseteq \{ x \mid x \leq j \}$, or
(II.i) $\text{content}(\sigma) \subseteq L$,
(II.ii) $W_{LN_M(\sigma)} \cap \{ x \mid x \leq \max(L) \} \subseteq L$,
(II.iii) For all $\tau$ such that $\text{content}(\tau) \subseteq L$, $LN_M(\sigma) = LN_M(\sigma \tau)$.
(II.iv) For all $n \leq |\sigma|$, $\min(W_{LN_M(\sigma[n])} \cap \mathbb{L} \cap \{ x \mid x \leq \max(\text{content}(\sigma[n])) \}) = \min(W_{LN_M(\sigma[n]), j} \cap \mathbb{L} \cap \{ x \mid x \leq \max(\text{content}(\sigma[n])) \})$.

Note that one can do the above search by dovetailing over all pairs $(\sigma, j)$, such that each pair gets infinitely many chances, and first we check if (I) above
holds, and if not, check if (II) holds. One can find in the limit a $(\sigma, j)$ such that
(I) or (II) holds, if such a $(\sigma, j)$ exists. (Note that, if (I) does not hold for a
particular $(\sigma, j)$, then one can determine $\chi_L[j]$, as $L$ contains an element $> j$.
Thus, one can determine violation of (II) in a way similar to that done in the
proof of Proposition 6).

For any candidate $(\sigma, j)$, if (I) seems to hold, $M'$ outputs a grammar for
$\text{content}(T) \cap \{ x \mid x \leq j \}$, and if case (II) seems to hold, $M'$ outputs $LN_M(\sigma)$. 
If none of (I) and (II) hold, we move on to the next candidate.

Now, due to checking of the conditions (I) and (II), $M'$ can only converge
to a conjecture of $M$ on a stabilizing sequence (for $M$ on $L$), due to success of
(II) or to a conjecture for finite language due to success of (I). For $L \in \mathcal{L}$, in the
former case, by condition (b) in the proposition, we have $\text{BNCEx}$-identification,
and for the latter case we clearly have $\text{BNCEx}$-identification due to explicitly
outputing grammar for the input language, which is finite.

Furthermore, every finite language $L$ would eventually lead to convergence
due to success of (I) or earlier due to some stabilizing sequence for $M$ on $L$. 
Also, every infinite language $L \in \mathcal{L}$, would eventually lead to convergence due
to presence of some stabilizing sequence for $M$ on $L$.

From above, $\text{BNCEx}$ identification of $\mathcal{L}$ by $M'$ follows. 

We now consider several variants of $\text{NCEx}$ model where the negative examples
may not appear immediately, nor may they appear for all conjectures
enumerating a non-subset of $L$. These variants reflect complexity constraints on
the teacher – yet differently from the models with limited size of negative counterexamples. As formal definitions of the models to be presented are technically
rather complex, we proceed below somewhat informally.

**Definition 15.** Consider the following models for delayed negative counterexamples.

D1: The learner eventually receives a negative counterexample for every
hypothesis which enumerates a non-subset of $L$. We do not constrain when this
negative counterexample appears, nor is the negative counterexample tagged
with the hypothesis to which it is a counterexample.

D2: If the learner converges to a hypothesis, and this hypothesis
enumerates a non-subset of \( L \), then the learner will eventually receive a negative coun-
terexample for it (idea here is that abandoned hypothesis may not get negative coun-
terexample).

D3: For all \( m \), if the learner outputs a hypothesis at step \( m \) which enumer-
ates a non-subset of \( L \), then there exists some negative counterexample for a
hypothesis output at a step \( > m \) (here the idea is that once a grammar gets
a negative counterexample, one may consider all previously output non-subset
grammars addressed).

D4: If a grammar is output infinitely often by the learner, and this grammar
enumerates a nonsubset of \( L \), then the learner eventually receives a negative coun-
terexample for the grammar. We do not constrain when this negative coun-
terexample appears, nor is the counterexample tagged with the hypothesis to
which it is a counterexample.

Clearly, D2 is contained in each of D1, D3 and D4. Thus showing that
\( \text{NCEx} = D2 \) means the collapsing of all these variants to \( \text{NCEx} \). This in
some sense would show that the model we have chosen is reasonably robust.
The following, quite surprising result demonstrates that all the above models do
collapse to \( \text{NCEx} \): indefinite delays do not constrain learners if positive data
and negative counterexamples are eventually available!

\textbf{Theorem 16.} \( \text{NCEx} = D2 \).

\textit{Proof.} Clearly, \( D2 \subseteq \text{NCEx} \). We show that \( \text{NCEx} \subseteq D2 \). Suppose \( M \) \text{NCEx}-
identifies \( L \). We define a \( D2 \) learner \( M' \) as follows:

\( M' \) tries to search for a stabilizing sequence for \( M \) on \( L \).

\( M' \) on the input text \( T \) does the following:

\( M' \) on text \( T \) for a language \( L \).

For each pair \((\sigma,j)\):

1. First determine \( \chi_L[j] \). (Note that \( M' \) can determine if a particular el-
   ement \( x \) is in \( L \) or not, by repeatedly outputing a grammar for \( \{x\} \)
   until it either receives \( x \) in text or \( x \) as negative example (one of these
   must happen, otherwise \( M' \) converges to grammar for \( \{x\} \) on \( T \), but
does not receive the required positive/negative example). Thus it can
determine \( \chi_L[j] \).

2. If content(\( \sigma \)) \( \not\subseteq \) content(\( T \)), then go to next iteration of the loop (note
   that, whether content(\( \sigma \)) \( \subseteq \) content(\( T \)), can be determined similarly
to step 1 above).

3. Else, assume the following property:

\( (P1) \) for all \( \tau \subseteq \sigma \),
\( \min(W_{L_{M(\tau)}} \cap L) = \min(W_{L_{M(\tau,j)}} \cap L) \)

(This is property (iv) in definition of stabilizing sequence).
and calculate \( L_{M(\tau)} \), for \( \tau \subseteq \sigma \), and

\[ S = \{ \text{LN}_M(\tau) \mid W_{\text{LN}_M(\tau)} \subseteq L \} \] (i.e., the grammars output by \( \text{LN}_M \) on prefixes of \( \sigma \), for which \( \# \) was given as negative example).

4. Output a grammar for \( \bigcup_{i \in S} W_i \).

5. Idle until at least one of the following is satisfied:
   (a) there exists a negative counterexample for \( \bigcup_{i \in S} W_i \). (This verifies property (ii) in the definition of stabilizing sequence and part of property (P1) above (the part where \( W_{\text{LN}_M(\tau)} \cap L = \emptyset \)).
   (b) assuming (a) does not hold, check if property (P1) above is violated. (Note that this can be verified, assuming (a) above does not hold, by enumerating the elements output by \( \text{LN}_M(\sigma[n]) \)).
   (c) assuming, (a) and (b) do not hold, check if there exists a \( \tau \) such that content(\( \tau \)) \( \subseteq L \), and \( \text{LN}_M(\sigma) \neq \text{LN}_M(\sigma \tau) \). (This verifies property (iii) in stabilizing sequence).

6. If one of (a) to (c) succeed, then go to the next iteration of the For loop.

EndFor

Now note that, if in any iteration of the For loop, (a)–(c) do not succeed, then we have that \( (\sigma,j) \) is a stabilizing sequence of \( M \) on \( L \), and \( L \supseteq \bigcup_{i \in S} W_i \supseteq W_{\text{LN}_M(\sigma)} = L \). Thus, \( M' \) converges to correct grammar. On the other hand, if one of (a) to (c) succeed, then \( (\sigma,j) \) is not a stabilizing sequence for \( M \) on \( L \).

It is now easy to verify that, if there exists a stabilizing sequence for \( M \) on \( L \), then for some such stabilizing sequence \( (\sigma,j) \) the conditions (a)–(c) are not satisfied, and \( M' \) above converges to a grammar for \( \bigcup_{i \in S} W_i \) (where \( S \) is as in the iteration for \( (\sigma,j) \)).

Thus, \( M' \) D2-identifies any language NCEx-identified by \( M \).

Note that proof for the above theorem did not use the exact negative counterexample, but just the fact that a negative counterexample existed for the latest conjecture. In other words, our basic (and the most powerful) learning model is equivalent to the one where a learner gets only answers “yes” or “no” to the subset queries (when it is tested if the current conjecture generates a subset of the target language)!

As D4 \( \supseteq \) D2 and D3 \( \supseteq \) D2 and D1 \( \supseteq \) D2, we have that all of these are same as NCEx.

6 Bc-type Learning With Negative Counterexamples

In this section we explore Bc-style learning from positive data and negative counterexamples. First we show that, for Bc-style learning, similarly to Ex-style learning, our basic model is equivalent to learning with the least negative counterexamples.

Proposition 8. (a) NCBc = LNCBc.
   (b) LNCBc \( \subseteq \) InfBc.
Proof. (a) Clearly, $\text{NCBc} \subseteq \text{LNCBc}$. For $\text{LNCBc} \subseteq \text{NCBc}$, note that, for any grammar $i$, one can get the least negative counterexample from arbitrary negative counterexample $y$ by conjecturing grammars for the following languages: $W_y \cap \{x \mid x \leq y\}$, for all different values of $x \leq y$. Note that this search introduces extra wrong conjectures, however, since in Bc-type learning all but finitely many grammars output are for the input language, this does not hurt the simulation.

(b) Suppose $\text{M NCBc}$-identifies $L$. Define machine $\text{M}'$ as follows.

For an informant $I$ for $L$, define text $T$ for $L$ as follows:

$$T(i) = \begin{cases} x, & \text{if } I(x) = 1; \\ \#, & \text{otherwise}. \end{cases}$$

On input $I[n]$, output $\text{M}(T[n], \tau)$, where $\tau$ is of length $n$, where for $i < n$,

$$\tau(i) = \begin{cases} \#, & \text{if } W_{\text{M}(T[i], \tau[i]), n} \cap \{x < n \mid I(x) = 0\} = \emptyset; \\ \min(W_{\text{M}(T[i], \tau[i]), n} \cap \{x < n \mid I(x) = 0\}), & \text{otherwise}. \end{cases}$$

Now if $\text{M LNCBc}$-identifies $L$, then for all but finitely many $n$, the negative answers given for conjectures of $\text{M}$ on $T$ are correct and hence $\text{M}'$ reproduces the output of $\text{M}$ on all except for finitely many initial segments of $T$. Thus, $\text{M}'$ $\text{InfBC}$-identifies $L$.

Our next result shows that, to learn a language, sometimes even for Bc-style learning, positive data and negative counterexamples are not enough - the learner must have access to all negative data. In particular, limitations on the learning power of our basic Bc-style model are established.

**Theorem 17.** $\text{InfEx} - \text{NCBc} \neq \emptyset$.

**Proof.** Let $\mathcal{L} = \{L \mid (\exists e)[\min(L) = 2e] \land \begin{align*} (i) & \quad [L = W_e \text{ and } (\forall x \geq e)[L \cap \{2x, 2x + 1\} \neq \emptyset]], \\ \text{OR} & \quad (ii) (\exists x > e)[L \cap \{2x, 2x + 1\} = \emptyset, \land (\forall y > 2x + 1)[y \in L]] \end{align*} \}$

It is easy to verify that $\mathcal{L} \in \text{InfEx}$. A learner can easily find $e$ as above, and whether there exists $x > e$ such that both $2x, 2x + 1$ are not in the input language. This information is sufficient to identify the input language.

We now show that $\mathcal{L} \not\in \text{NCBc}$. Intuitively, the idea is that a learner which learns a language satisfying clause (ii) above, must output infinitely many grammars properly extending the input seen up to the point of conjecture. By repeatedly searching for such input and conjectures, one can identify one element of each such conjecture as negative counterexample, allowing one to construct $W_e$ as needed for clause (i) as well as diagonalizing out of $\text{NCBc}$. Note that we needed a pair $\{2x, 2x + 1\}$, to separate (i) from (ii) as one of the elements may be needed for giving the negative counterexamples as mentioned above. We now proceed formally.
Suppose by way of contradiction that machine $M_{NCBc}$ identifies $L$. Then by the Kleene Recursion Theorem [Rog67] there exists a recursive function $e$ such that $W_e$ may be defined as follows.

Initially, let $W_e = \{2e, 2e+1\}$ and $e_0$ be such that $\text{content}(e_0) = \{2e, 2e+1\}$. Intuitively $\text{Cntrxmlps}$ denotes the set of elements frozen to be outside the diagonalizing language being constructed. Initially $\text{Cntrxmlps} = \{x \mid x < 2e\}$. Intuitively, $\text{NegSet}$ is the set of conjectured grammars for which we have found a negative counterexample (in $\text{Cntrxmlps}$). Initially let $\text{NegSet} = \emptyset$. $\text{nexx}(j)$ is a function which gives, for $j \in \text{NegSet}$, a negative counterexample from $\text{Cntrxmlps}$. For the following, let $\gamma_\tau$ be a sequence of length $|\tau|$ defined as follows. For $i < |\tau|$, 

$$
\gamma_\tau(i) = \begin{cases} 
\text{nexx}(M(\tau[i], \gamma_\tau[i])), & \text{if } M(\tau[i], \gamma_\tau[i]) \in \text{NegSet}; \\
\#, & \text{otherwise.}
\end{cases}
$$

(where the value of NegSet is as at the time of above usage).

Let $x_0 = 2e + 2$. Intuitively, $x_s$ is the least even element greater than $\text{max(content}(e_s) \cup \text{Cntrxmlps})$. Also we will have the invariant that at start of stage $s$,

(i) every element $< x_s$ is either in content($e_s$) or Cntrxmlps and

(ii) content($e_s$) consists of elements enumerated in $W_e$ before stage $s$.

Go to stage 0.

**Stage $s$**

1. Dovetail steps 2 and 3 until step 2 or 3 succeed. If step 2 succeeds before step 3, if ever, then go to step 4. If step 3 succeeds before step 2, if ever, then go to step 5.

Here we assume that if step 3 can succeed by simulating $M(\tau, \gamma_\tau)$ for $s$ steps, then step 3 succeeded first (and for the shortest such $\tau$), otherwise whichever of these steps succeeds first is taken. (So some priority is given to step 3 in the dovetailing).

2. Search for a $\tau \supseteq e_s$ such that

\[
\text{content}(\tau) \subseteq \text{content}(e_s) \cup \{x \mid x \geq x_s + 2\},
\]

$M(\tau, \gamma_\tau) \notin \text{NegSet}$ and

$W_{M(\tau, \gamma_\tau)}$ enumerates an element not in content($\tau$).

3. Search for a $\tau \subseteq e_s$ such that $M(\tau, \gamma_\tau) \notin \text{NegSet}$ and $W_{M(\tau, \gamma_\tau)}$ enumerates an element not in content($e_s$).

4. Let $\tau$ be as found in step 2, and $j = M(\tau, \gamma_\tau)$, and $z$ be the element found to be enumerated by $W_j$ which is not in content($\tau$).

Let $\text{NegSet} = \text{NegSet} \cup \{j\}$.

Let $\text{Cntrxmlps} = \text{Cntrxmlps} \cup \{z\}$.

Let $\text{nexx}(j) = z$.

Let $x_{s+1}$ be the least even number $> \text{max(content}(\tau) \cup \{x_s, z\})$.

Enumerate $\{x \mid x_s \leq x < x_{s+1}\} \setminus \{z\}$ in $W_e$.

Let $\sigma_{s+1}$ be an extension of $\tau$ such that content($\sigma_{s+1}$) = $W_e$ enumerated until now.

Go to stage $s + 1$. 

5. Let τ be as found in step 3, and \( j = M(\tau, \gamma_\tau) \), and \( z \) be the element found to be enumerated by \( W_j \) which is not in \( \text{content}(\sigma_s) \).

Let \( \text{NegSet} = \text{NegSet} \cup \{ j \} \).

Let \( \text{Cntrexlms} = \text{Cntrexlms} \cup \{ z \} \).

Let \( \text{nex}(j) = z \).

Let \( x_{s+1} \) be the least even number > \( \max(\{ x_s, z \}) \).

Enumerate \( \{ x \mid x_s \leq x < x_{s+1} \} - \{ z \} \) in \( W_e \).

Let \( \sigma_{s+1} \) be an extension of \( \sigma_s \) such that \( \text{content}(\sigma_{s+1}) = W_e \) enumerated until now.

Go to stage \( s+1 \).

End stage \( s \)

We now consider the following cases:

Case 1: Stage \( s \) starts but does not finish.

In this case let \( L = W_e \cup \{ x \mid x \geq x_s + 2 \} \). Note that, due to non-success of steps 2 and 3, the negative information given in computation of \( \gamma_\tau \) based on \( \text{NegSet} \) is correct. Thus, for any text \( T \) for \( L \) extending \( \sigma_s \), for \( n > \| \sigma_s \| \), \( M(T[\tau_n], \gamma_T[\tau_n]) \) \( \in \text{NegSet} \) or it enumerates only a finite set (otherwise step 2 would succeed). Thus, \( M \) does not \( \text{NCBc-identify} \) \( L \).

Case 2: All stages finish.

Let \( L = W_e \). Let \( T = \bigcup_{s \in N} \sigma_s \). Note that \( T \) is a text for \( L \). Let \( \text{Cntrexlms} \) denote the set of all elements which are ever placed in \( \text{Cntrexlms} \) by the above construction. Note that eventually, any conjecture \( j \) by \( M \) on \( (T, \gamma_T) \) which enumerates an element not in \( L \), belongs to \( \text{NegSet} \), with a negative counterexample for it belonging to \( \text{Cntrexlms} \) (given by \( \text{nex}(j) \)). This is due to eventual success of step 3, for all \( \tau \subseteq T \), for which \( M(\tau, \gamma_\tau) \subseteq L \) (due to priority assigned to step 3).

If there are infinitely many \( \tau \subseteq T \) such that \( M(\tau, \gamma_\tau) \not\subseteq L \), then clearly, \( M \) does not \( \text{NCBc-identify} \) \( L \). On the other hand, if there are only finitely many such \( \tau \), then clearly all such \( \tau \) would have been handled by some stage \( s \), and beyond stage \( s \), step 3 would never succeed. Thus, beyond stage \( s \) computation of \( M(\tau, \gamma_\tau) \), as at stage \( s \) step 2, is always correct (with negative counterexamples given, whenever necessary), and step 2 succeeds infinitely often. Thus again infinitely many conjectures of \( M \) on \( (T, \gamma_T) \) are incorrect (and enumerate an element of \( L \)), contradicting the hypothesis.

From above cases it follows that \( M \) does not \( \text{NCBc-identify} \) \( L \). Theorem follows.

Our next result shows that all classes of languages learnable in our basic \( \text{Ex} \)-style model with arbitrary finite number of errors in almost all conjectures can be learned without errors in the basic \( \text{Bc} \)-style model. Note the contrast with learning from texts where \( \text{TxtEx}^{2j+1} - \text{TxtBc}^j \neq \emptyset \) [CL82].

**Theorem 18.** \( \text{NCEx}^* \subseteq \text{NCBc} \).

**Proof.** Suppose \( M \) \( \text{NCEx}^* \)-identifies \( L \). Define \( M' \) as follows. \( M' \) on (positive) input \( \sigma \) is obtained by simulating \( M \) on input \( \sigma \). Suppose \( M \) outputs grammar
i. If this is the first time $M$ has output $i$, then $M'$ also outputs $i$, and passes to $M$ any negative counterexample obtained. If $i$ has been previously output, then in the simulation $M$ receives the negative counterexample received the last time $i$ was output by $M'$, and $M'$ outputs a grammar for \( W_i \cup \text{content}(\sigma) - \{x\} \). $x$ has been received by $M'$ as negative information up to now. Now, if the final grammar of $M$ on the input text makes only finitely many errors, then all these errors are patched by $M'$ (positive errors are patched due to addition of content(\( \sigma \)); negative errors are patched due to fixing of all negative errors, one by one, as received by $M'$). Thus, $M'$ NCBC-identifies $L$.

Next theorem establishes yet another limitation on the learning power of our basic Bc-style learning; some languages not learnable in this model can be Bc-learned without negative counterexamples if only one error in almost all conjectures is allowed.

**Theorem 19.** For all $n \in N$, $\text{TtxtBc}^1 - \text{NCBC} \neq \emptyset$

**Proof.** Follows from $\text{TtxtBc}^1 - \text{InfBc} \neq \emptyset$ [CL82] and Proposition 8.

Now we turn to Bc-style learning with limited size of negative counterexamples. First, note that Theorem 8 gives us: $\text{BNCE} - \text{TtxtBc}^* \neq \emptyset$. In other words, some languages Ex-learnable with negative counterexamples of limited size cannot be Bc-learned without counterexamples even with an arbitrary finite number of errors in almost all conjectures. On the other hand, as the next theorem shows, some languages learnable in our basic Ex-style learning with negative counterexamples cannot be learned in Bc-model with limited size of negative counterexamples even if an arbitrary finite number of errors is allowed in almost all conjectures.

**Theorem 20.** $\text{NCE} - \text{BNCE} \neq \emptyset$.

**Proof.** The class used for separating $\text{BF}^h \text{NCE} - \text{BNCE}$ in Theorem 9, \( \text{INIT} \cup \{N\} \), is not in $\text{BNCE}^*$, as negative examples are not relevant and the class itself is not in $\text{TtxtBc}^*$ by Proposition 3.

Similarly, from the proof of Theorem 10 we have,

**Theorem 21.** Suppose $h, h' \in \text{INIT}$ such that $h'(x) > h(x)$ for infinitely many $x$. Then $\text{BF}^h \text{NCE} - \text{NRBF}^h \text{NCE}^* \neq \emptyset$.

Thus, similarly to the Ex-style model, we have a hierarchy on the Bc-style models depending on the recursive factor limiting the size of negative counterexamples.

Our next result establishes a limitation on the learning power of Bc-style learning with negative counterexamples of limited size allowing arbitrary finite number of errors in almost all conjectures: there are some indexed classes of languages not learnable in this model (as Theorem 1 showed, all such classes are Ex-style learnable in the basic model).
Theorem 22. There exists an indexed family not in BNCBc°.

Proof. The class used in Theorem 9, INIT ∪ \{N\}, is an indexed family not in BNCBc°.

Corollary 5. InfEx – BNCBc° \(\neq\) 0.

Now we establish one of our most surprising results: there exists a Bc-style learner with negative counterexamples, allowing just one error in almost all conjectures, with the "ultimate power" - it can learn the class of all recursively enumerable languages!

Theorem 23. \(\mathcal{E} \in \text{NCBc}^1\).

Proof. First we give an informal idea of the proof. Our learner can clearly test if a particular \(W_s \subseteq L\). Given an arbitrary initial segment of the input \(T[n]\), we will want to test if \(\text{content}(T[n]) \not\subseteq W_s\) for any r.e. set \(W_s \subseteq L\), where \(L\) is a target language. Of course, the teacher cannot directly answer such questions, since \(W_s\) might not be the target language (note also that the problem is undecidable). However, the learner finds a way to encode this problem into a current conjecture and test if the current conjecture generates a subset of the target language. In order to do this, the learner potentially makes one deliberate error in its conjecture! We now proceed formally.

Define \(M\) on the input text \(T\) as follows. Initially, it outputs a grammar for \(N\). If it does not generate a negative counterexample, then we are done. Otherwise, let \(c\) be the negative counterexample. Go to stage 0.

Stage \(s\)
1. Output grammar \(s\). If it generates a negative counterexample, then go to stage \(s + 1\).
2. Else,
   For \(n = 0\) to \(\infty\) do:
   - Output a grammar for the language \(X\) where:
     \[
     X = \begin{cases} 
     \emptyset, & \text{if content}(T[n]) \not\subseteq W_s ; \\
     W_s \cup \{c\}, & \text{otherwise} .
     \end{cases}
     \]
   - If it does not generate a negative counterexample, then go to stage \(s + 1\),
     Otherwise continue with the next iteration of For loop.
   EndFor

End stage \(s\)

We now claim that above \(M\) \(\text{NCBc}^1\)-identifies \(\mathcal{E}\). Clearly, if \(L = N\), then \(M\) \(\text{NCBc}^1\)-identifies \(L\). Now suppose \(L \neq N\). Let \(c\) be the negative counterexample received by \(M\) for \(N\). Let \(j\) be the least grammar for \(L\), and \(T\) be a text for \(L\). We claim that all stages \(s < j\) will finish, and stage \(j\) will not finish. To see this consider any \(s < j\).
Case 1: \( W_s \not\subseteq L \).
In this case note that step 1 would generate a negative counterexample, and thus we will go to stage \( s + 1 \).

Case 2: Not Case 1 (i.e., \( W_s \subseteq L \) but \( L \not\subseteq W_s \)).
In this case, let \( m \) be least such that \( \text{content}(T[m]) \not\subseteq W_s \). Then, in the iteration of For loop in step 2, with \( n = m \), the grammar output is for \( \emptyset \). Thus, there is no negative counterexample, and algorithm proceeds to stage \( s + 1 \).

Also, note that in stage \( s = j \), step 1 would not get a negative counterexample, and since \( c \not\in L \), every iteration of For loop will get a negative counterexample. Thus, \( M \) keeps outputing grammar for \( W_j \cup \{ c \} \). Hence \( M \text{NCB}^1 \)-identifies \( L \). Thus, we have that \( M \text{NCB}^1 \)-identifies \( E \). ■

Since \( E \in \text{InfBc}^* \), we have

**Corollary 6.** (a) \( \text{NCB}^1 = \text{InfBc}^* \).
(b) For all \( a \in N \cup \{ * \} \), \( \text{NCB}^a = \text{LNCB}^a \).

The following corollary shows a contrast with respect to the case when there are no errors in conjectures (Proposition 8 and Theorem 17). What a difference just one error can make! Using the fact that \( \text{InfBc}^n \subseteq \text{InfBc}^* \) (see [CS83]), we get

**Corollary 7.** For all \( n > 0 \), \( \text{InfBc}^n \subset \text{NCB}^n = \text{NCB}^1 \).

The ideas of the above theorem are now employed to show that all infinite recursively enumerable languages can be learned in our basic \( \text{Bc} \)-style model with negative counterexamples of limited size allowing just one error in almost all conjectures. Note that, as we demonstrated in Theorem 22, contrary to the case when there are no limits on the size of negative counterexamples, such learners cannot learn the class of all recursively enumerable languages.

**Theorem 24.** Let \( L = \{ L \in E \mid L \text{ is infinite} \} \). Then \( L \in \text{BNCB}^1 \).

**Proof.** The idea is essentially the same as showing \( E \in \text{NCB}^1 \), (Theorem 23) except that now
(i) we need to keep conjecturing \( N \) until we get negative counterexample, if any, and
(ii) we need to do step 1 check in every iteration of the For loop in step 2 (to make sure that every negative counterexample gets a chance, since \( \text{BNC} \) model only allows negative counterexample below the maximum element in the input).

We omit the details. ■

As there exists a class of infinite languages which does not belong to \( \text{InfBc}^n \) (see [CS83]), we have

**Corollary 8.** For all \( n \in N \), \( \text{BNCB}^1 - \text{InfBc}^n \neq \emptyset \).

Thus, \( \text{BNCB}^n \) and \( \text{InfBc}^n \) are incomparable for \( m > 0 \). The above result does not generalize to \( \text{InfBc}^* \), as \( \text{InfBc}^* \) contains the class \( E \).
Now, based on the ideas similar to the ones used in Theorem 23, we show that all classes of languages $\mathbf{BC}^n$-learnable without negative counterexamples can be $\mathbf{BC}$-learned with negative counterexamples of limited size when one error in almost all conjectures is allowed.

**Theorem 25.** For all $n \in \mathbb{N}$, $\text{TxtBC}^n \subseteq \text{BNCBC}^1$.

**Proof.** Suppose $\mathbf{M \; TxtBC}^n$-identifies $\mathcal{L}$. Define $\mathbf{M}'$ as follows.

Initially, on input $T[m]$, for $m = 0, 1, 2, \ldots$, $\mathbf{M}'$ outputs grammar for the language:

$$
\begin{cases}
\text{content}(T[m]), & \text{if } \text{card}(W_{\mathbf{M}'(T[m])}) \leq \text{card(content}(T[m])) + n; \\
N, & \text{otherwise}.
\end{cases}
$$

This continues until and unless a negative counterexample is received. Note that if negative counterexample is never received then either

(i) input is a finite set, and eventually only first case above applies, and thus $\mathbf{M}'$ is outputing only correct grammars from some point onwards,

or

(ii) input is an infinite member of $\mathcal{L}$, and eventually only second case above applies, and thus input must be $N$, and $\mathbf{M}'$ is outputing only correct grammars from some point onwards,

or

(iii) input is not in $\mathcal{L}$.

So, if above process does not generate a negative counterexample, then we are done. Otherwise, let $c$ be the negative counterexample. Go to stage 0.

Stage $s$

For $m = s$ to $\infty$ do:

(Note that we start with $m = s$).

1. Output a grammar for:

$$
\begin{cases}
\text{content}(T[m]), & \text{if } \text{card}(W_{\mathbf{M}(T[m])}) \leq \text{card(content}(T[m])) + n; \\
W_s, & \text{otherwise}.
\end{cases}
$$

If it generates a negative counterexample, then go to stage $s+1$. (note that negative counterexample can be generated only if the second case above applied).

2. Output a grammar for:

$$
L = \begin{cases}
\text{content}(T[m]), & \text{if } \text{card}(W_{\mathbf{M}(T[m])}) \\
& \leq \text{card(content}(T[m])) + n \\
& \text{or content}(T[m]) \not\subseteq W_s;
\text{content}(T[m]) \cup W_s \cup \{c\}, & \text{otherwise}.
\end{cases}
$$

If it does not generate a negative counterexample, then go to stage $s+1$.

Otherwise continue with the next iteration of For loop.

EndFor

End stage $s$
We now claim that above $\textbf{M} \text{ NCBc}_1$-identifies $\mathcal{L}$. Let $L \in \mathcal{L}$ and $T$ be a
text for $L$. Based on the discussion before staging construction, assume that we
reach stage 0 (otherwise we are already done).

Now, suppose $L$ is finite and $T$ is a text for $L$. Then, for some $t$, for all
$m \geq t$, content$(T[m]) = L$ and $\textbf{M}(T[m])$ outputs a grammar for an $n$-variant of
$L$. Thus, irrespective of whether we converge to a stage or have infinitely many
stages, eventually only grammar for $L$ would be output by $\textbf{M}'$, as first clause
applies for all $m \geq t$ in the staging construction.

So suppose $L$ is infinite and $T$ is a text for $L$. Then for some $t$, for all $m \geq t$,
$\textbf{M}(T[m])$ is a grammar for infinite set. Now note that, any stage $j$ for which
$W_j \neq L$ would be exited (same argument as done in proof of $\mathcal{E} \in \text{NCBc}_1$
applies here). Furthermore, for any $j \geq t$, such that $j$ is a grammar for $L$, the
stage would not be exited. (We may exit some stages $j < s$, for which $W_j$
is a grammar for $L$, due to the extra stuff added in clause 1 of step 2). Thus,
everually we reach a stage $s = j$ such that $W_j$ is a grammar for $L$, and the
construction does not leave stage $s$. From this point onwards, $\textbf{M}$ only outputs a
grammar for $W_s$ or for $W_s \cup \{c\}$. Theorem follows.

Similarly, one can show

**Theorem 26.** $\text{TxtEx}^* \subseteq \text{NCBc}_1$.

Similarly to the case of $\textbf{Ex}$-style learning, $\text{BNCBc}$ and $\text{NCBc}$ models turn
out to be equivalent for the classes of infinite languages.

**Theorem 27.** Suppose $\mathcal{L}$ consists of only infinite languages. Then $\mathcal{L} \in \text{NCBc}$
iff $\mathcal{L} \in \text{BNCBc}$.

**Proof.** The idea of the proof is similar to the proof of Theorem 7. The main
difference being that we do not patch errors, and the argument about eventually
being able to give right answers in the simulation being based on “finitely
many wrong conjectures done by $\text{NCBc}$-learner”, rather than “finitely many
conjectures by $\text{NCEx}$-learner.” We now proceed formally.

Clearly, if $\mathcal{L} \in \text{BNCBc}$, then $\mathcal{L} \in \text{NCBc}$. So we only need to show that
if $\mathcal{L} \in \text{NCBc}$ then $\mathcal{L} \in \text{BNCBc}$. Suppose $\textbf{M} \text{ NCBc}$-identifies $\mathcal{L}$. Define $\textbf{M}'$
as follows. $\textbf{M}'$ on the input text $T$ of positive data for an infinite language $L$
behaves as follows. Initially let NegSet = $\emptyset$. Intuitively, NegSet denotes the set
of grammars for which we know a negative counterexample. For $j \in \text{NegSet}$,
$\text{ncez}(j)$ would denote a negative counterexample for $j$. For ease of presentation,
we will let $\textbf{M}'$ output more than one conjecture (one after another) at some
input point and get negative counterexamples for each of them. This is for ease
of presentation and one can always spread out the conjectures.

Stage $s$ (on input $T[s]$)
1. Simulate $\textbf{M}$ on $T[s]$, by giving negative counterexamples to any conjectures
   $j \in \text{NegSet}$ by $\text{ncez}(j)$. Other grammars get $\#$ as counterexample.
2. Let $S$ be the set of conjectures output by $\textbf{M}$ on initial segments of $T[s]$. 
3. Output a grammar for $\bigcup_{i \in S} \text{NegSet}_i W_i$.
4. If there is no negative counterexample, then go to stage $s + 1$.
5. Else (i.e., there is a negative counterexample), output one by one, elements of $S - \text{NegSet}$. For each $i \in S - \text{NegSet}$, if a negative counterexample is obtained, then place $i$ in NegSet and define $n_{cex}(i)$ to be this negative counterexample.
6. Go to stage $s + 1$.
End Stage $s$.

Now suppose $T$ is a text for $L \in \mathcal{L}$ and consider the above construction for $M'$. Due to output at step 3, eventually any grammar output by $M$ on text $T$ (when negative counterexamples are based on NegSet and $n_{cex}$), which enumerates a non-subset of $L$ would receive a negative counterexample. Thus, as $M$ NCBc-identifies $L$, for all but finitely many stages $s$, all the answers given to $M$ in step 1 would be correct. Thus, the grammar output in step 3 would be correct for all but finitely many stages, and $M'$ BNCBc-identification $L$.

We now mention some of the open questions regarding behaviourally correct learning when the size of the negative counterexamples is bounded.

Open Question: Is BNCBc$^n$ hierarchy strict?

Open Question: Is TxtBc$^*$ $\subseteq$ BNCBc$^1$?
